Why and How to Reshape a Pandas Dataframe from Wide to Long

A Simple Piece of Code Does the Trick

	Country Name	Series Name	Series Code	Country Code	Year	GDP
0	Afghanistan	GDP (current US\$)	NY.GDP.MKTP.CD	AFG	1960-01-01	5.377778e+08
1	Albania	GDP (current US\$)	NY.GDP.MKTP.CD	ALB	1960-01-01	NaN
2	Algeria	GDP (current US\$)	NY.GDP.MKTP.CD	DZA	1960-01-01	2.723593e+09
3	American Samoa	GDP (current US\$)	NY.GDP.MKTP.CD	ASM	1960-01-01	NaN
4	Andorra	GDP (current US\$)	NY.GDP.MKTP.CD	AND	1960-01-01	NaN

As data scientists, we know that data does not always come to us with the most desirable format that's ready for analysis or visualization. Reshaping a table or pandas dataframe from wide to long format falls into one of those scenarios where we need to apply some 'tricks' to the data to proceed with the analysis.

This is a typical example of a ‘wide-format’ table. For each country, we have its GDP in each year in a separate column, with a total of 61 columns/years of GDP data. Basically, the table extends by year horizontally, making it very wide, thus the name ‘wide-format’.

While a ‘wide-format’ table seems easy to read and is quite common in reality, it is very difficult to plot in Python. We need to ‘transpose’ the table/dataframe so that we have one variable that represents the time column (in our case, the ‘Year’) and another column that has the value (in our case, the GDP) for each year.

So how to do it in Python? In order to reshape the dataframe from wide to long, we will need to use a pandas function called `pd.melt()`. In the code below:

Line 2: we get the list of the 'Year' columns from the pandas dataframe. These are the columns that are to be transposed.

Line 3: we specify which variables in the dataframe are 'id_var' — which basically are the columns that are not to be changed/transposed (i.e., the first four columns in our dataframe). We will also need to specify which variables in the dataframe are to be transposed — in our case, all the year variables (1960[YR1960], 1961[YR1961], 1962[YR1962], etc.)

[Open in app](#)

The reshaped long-format dataframe will have a ‘variable’ column that represents the year, and a ‘value’ column that represents the value of each year, i.e., GDP. The column names ‘variable’ and ‘value’ are both default names given by `pd.melt()`.

	Country Name	Series Name	Series Code	Country Code	variable	value
0	Afghanistan	GDP (current US\$)	NY.GDP.MKTP.CD	AFG	1960 [YR1960]	537777811.111111
1	Albania	GDP (current US\$)	NY.GDP.MKTP.CD	ALB	1960 [YR1960]	NaN
2	Algeria	GDP (current US\$)	NY.GDP.MKTP.CD	DZA	1960 [YR1960]	2723593384.78054
3	American Samoa	GDP (current US\$)	NY.GDP.MKTP.CD	ASM	1960 [YR1960]	NaN
4	Andorra	GDP (current US\$)	NY.GDP.MKTP.CD	AND	1960 [YR1960]	NaN

Bonus: Create a Bar Chart Race Using the Reshaped Dataframe

Now we can easily create a bar chart race animation from the **reshaped** dataframe using `raceplotly`. If you don't have `raceplotly`, you can install it by running the following command line:

```
pip install raceplotly
```

The most important and required arguments in `raceplotly` are:

- `item_column` : name of the column representing the items/bars to be ranked ('Country_Name')
- `value_column` : name of the column representing the value/metric to be used for ranking ('GDP')
- `time_column` : name of the column representing the time variable ('Year')
